Abstract

The pre-diabetes stage is the period before the onset of type II diabetes, but not all children in the pre-diabetes stage suffering from type II diabetes. Childhood obesity has been linked with type II diabetes. These diseases can decrease the life expectancy of the child. **Aim:** The aim of the study was to evaluate effect of educational and exercise program on blood glucose level among pre-diabetic obese children. **Research design:** Quasi-experimental design was used to complete this study. **Settings:** This study was conducted in the classrooms in governmental schools at Benha city, the schools were named; Ibn Khaldun, El-Emam Mohamed Abdou, Hoda Shaarawy and Benha modern school. **Sample:** Convenient sample of (111) students. **Tool:** Tool was used to collected the study data: **An interviewing questionnaire** was used to collected data which include five parts: Personal characteristics of studied children, children's knowledge about pre-diabetic stage, children's knowledge about obesity, children's knowledge about diabetes mellitus and children physical examination. **Results:** The mean age of studied children was 11.3±7.4 years and 56.5% of children were females, same percentages were engaged in preparatory education and 55.5% living in urban areas. More than half of children had poor knowledge in preprogram implementation. However, after the application of the programs, majority of children had good knowledge. There were statistically significant differences between children’ knowledge in the preprogram and post program. **Conclusion:** This study concluded that, children in pre-diabetes period their knowledge was upgrading after implementation of the health education program were improved especially for diet, obesity and personal hygiene, exercise, laboratory examination and physical examination. Meanwhile, there were improvement in blood sugar level, blood pressure and decrease body weight as compared to preprogram. **Recommendation:** the study recommended that, further research to be carried out about causes of prediabetes in children because diabetes has become a major public health problem in Egypt. **Keywords:** Pre-diabetes, obesity, diabetes, children
Introduction

Prediabetes, elevated of fasting blood glucose, abnormal glucose tolerance, or both, is associated with an enhanced risk for development of type 2 diabetes in adults. Children with pre-diabetes have blood glucose levels that are higher than normal, but not high enough to be diagnosed as diabetes. Prediabetes can put children at increased risk of developing type 2 diabetes, heart disease, and stroke. Prediabetes children may have some of the symptoms of diabetes or even problems from diabetes already present (National Institute of Diabetes and Digestive and Kidney disease, 2014). Prediabetes in obese children and adolescents has been associated with several cardiovascular changes, increased arterial thickness and stiffness, increased intima media thickness due to elevation in systolic blood pressure (Haemer, et al., 2014).

The estimated number of obesity among adolescents (12–19 years) (2014) and school-aged children (6–11 years) (2014) was higher than among preschool-aged children (2–5 years) (2014) (Hales, et al., 2014). Childhood obesity is a serious problem in the United States putting children and adolescents at risk for poor health. Obesity prevalence among children and adolescents is still too high for children and adolescents aged 2-19 years (Centers for Disease Control and Prevention (CDC), 2014).

Diabetes is one of the most common chronic diseases of childhood. Estimated number of new diagnosed cases of type 1 and type 2 diabetes are increasing among young children in the United States, about 2.9 million people are living with diagnosed or undiagnosed diabetes, and about 2.8 million people younger than 20 years are living with diagnosed diabetes. The incidence of new diagnosed cases in type 1 diabetes in youth increased by about 1.8 percent each year. During the same period, the rate of new diagnosed cases of type 2 diabetes increased even more quickly, at 4.8 percent. Type 1 diabetes, the most common form of diabetes in young people, is a condition in which the body fails to make insulin. Causes of type 1 diabetes are still unknown. But, in type 2
diabetes, the body does not make or use insulin well. In the past, type 1 diabetes was extremely rare in youth, but it has become more common in recent years. Young children especially obese should be directly to examining, prevent, and treat diabetes (National Institutes of Health (NIH), 2015).

The incidence of diabetes continues to increase with more cases of type 1 and type 2 diabetes being diagnosed among children and adolescents each year. The incidence of type 1 diabetes worldwide is growing most rapidly in children under five years of age. Managing type 2 diabetes includes making healthy food choices and participating in regular physical activity. Medical management may include insulin, other injectable medications or oral medications. Management can vary from nutrition only, to oral diabetic medication, to insulin or specific combinations (Neill, et al., 2015). The methods of maintaining child's current weight or losing weight are needed to eat a healthy diet and increase physical activity. Success depends largely on child desire to helping the child to make these changes. One of the most important things for a child in pre-diabetes to do is make useful, concrete decisions on lifestyle changes and exercise. The child and his parents should be proactive and ask their healthcare professionals about healthy diet and exercise helps to maintain weight-loss and prevent regain (Boyse and Clark, 2015).

A primary role for nurses to provides necessary information for children with diabetes and their mothers in an effort to help children make informed about prevention and managing their condition. A diabetes nurse can be able helps in monitor and educate patients especially children about advanced practice, advanced diabetes management and education. A diabetes nurse has additional responsibilities such as adjusting the type and dosage of medication, providing nutritional therapy, exercise planning and providing behavioral and psychosocial counseling (Graduate Nursing Education, 2015).
Aim of the Study

The study aimed to evaluate effect of educational and exercise program on blood glucose level among pre-diabetic obese children through:

2. Developing and implementing educational and exercise program to reduce complications of pre-diabetes

3. Evaluating effect of educational and exercise program on children knowledge in pre-diabetes stage.

Research Hypotheses

- The health educational and exercise program will improve the knowledge and exercise ability of studied children regarding pre-diabetes stage
- The health educational and exercise program will improve the blood glucose level among obese pre-diabetic children.

Subjects and Methods

Research Design

Quasi-experimental design was utilized in the current study.

Setting

The study was carried out in the class rooms in governmental schools at Benha city, the schools were named; Ibn Khaldun, El-Emam Mohamed Abdou, Hoda Shaarawy and Benha modern school, to collect the study data.

Sample

Convenient sample of all obese students (111) from the previous mentioned settings; 25 child from Ibn Khaldun, 21 child from El-Emam Mohamed Abdou, 41 child from Hoda Shaarawy and 15 child from Benha.
modern in mentioned settings (selected sample after taking body mass index).

**Inclusion criteria:**

- Children aged from 6 to 15 years.
- Children having overweight
- Measure blood pressure by using sphygmomanometer
- Body weight and body mass index.

Body mass index (BMI) is an important measurement used to determine child have overweight, underweight, or at an ideal weight.

Underweight and overweight ranges in children:

- **Underweight:** BMI-for-age < 5th percentile
- **At risk of overweight:** BMI-for-age 5th percentile to < 95th percentile
- **Overweight:** BMI-for-age > 95th percentile

**The manual calculation is as follows:**

\[
\text{BMI} = \frac{\text{weight in pounds}}{[\text{height in inches} \times \text{height in inches}]} \times \sqrt{\text{height in inches}}
\]

\[
\text{BMI} = \frac{\text{weight in kilograms}}{[\text{height in meters} \times \text{height in meters}]}\]

- Measure blood sugar level (fasting blood sugar, random blood sugar and urine analysis)

1. A fasting blood sugar level below 100 mg/dL is considered normal, blood sugar level from 100 to 125 mg/dL is considered prediabetes and blood sugar level of 126 mg/dL considered higher indicates type 2 diabetes.

2. Random blood sugar test: A blood sample is taken at a random time. A random blood sugar level of 200 mg/dL considered higher suggests diabetes.

3. Make urine analysis.
Tools of data collection

The following data were collected by using the following tools:

- **An interviewing questionnaire** was used to collect data which include five parts: 1) A personal characteristics of the children as age, sex, educational stage and residence. 2) Children's knowledge about pre-diabetic stage. 3) Children, knowledge about diabetes mellitus which concerned with (diabetes, exercise, nutrition, body hygiene and laboratory investigation). 4) Children knowledge about obesity (define, causes, complication and method of treatment). 5) Children physical examination.

**Scoring system for children knowledge**

The studied children knowledge was calculated for each item as follows: knows and /or correct answer was scored (2), knows and incorrect answer was scored (1), while don't know was scored (0). According to the actual student's responses which consisted of 21 questions, their total level of knowledge was categorized as poor level (less than 21 degree), average level (from 21 -< 31 degree) or good level (from 31 - 41 degree).

**Validity:** Content validity was done through three experts from Faculty Members of pediatric Health Nursing and pediatrician in university hospital.

**Reliability:** Reliability coefficients were calculated for the questionnaire items. The coefficient alpha was 0.87.

**Ethical consideration:** All relevant ethical aspects were considered for ensuring the confidentiality of the collected data through; gaining oral consent for participation in the study, explaining the purpose of the study, and all participants have the right to refuse or continue in the study any time without giving any reasons.

**Pilot study:** was carried out on 11 child to assess the tool clarity, applicability, and time needed to fill in each sheet those who participated in the pilot study were included from the main study sample.
Field Work

A permission from faculty of nursing, to the central agency of statistics and mobilization were prepared and delivered to the administration of education in Qualyobia was taken in order to conduct the study. Permission from administration of education in Qualyobia was obtained, to enter the schools and conducting the study.

The actual field work was carried out from the beginning of January 211 to the end of February and data collection from beginning of March to the end of April 211. The researchers were available two days/week (Sunday and Monday,) from 8am-1pm. The children's were interviewed individually by the researchers to implement the program in the schools. The children who fulfilled the criteria were invited to participate after providing them with a simple and full explanation of the aim and process of the study to obtain their verbal informed consent. Handout about the health education and exercise program for studied children's about control of pre-diabetes stage was provided.

• **Theoretical part:** consists of 5 sessions, each researcher take (32-33) children for knowledge, every session contain (3-5) children.

• **Practical part:** Was carried out in 2 session to be (21) children in each session and divided on the three researchers to be (11) child's with each one. Each session started by setting objectives and preparation of the content which covered the reason behind the application of the sessions, Random blood sugar test and urine analysis test. Each child takes about 11-15 minutes for random blood sugar test and urine analysis test. Each child was allowed to perform the steps of each procedure in school class room under the supervision of researchers. The researchers were repeated procedures until the student mastered these skills. Demonstration and redemonstration were conducted in 2 sessions for each group.
The Educational Intervention:

-First Phase:

A pretest was carried out by using the previously mentioned tools to assess knowledge, reported practice, quality of life and self-efficacy of mothers’ and their children.

-Second Phase:

This phase included analysis of the pre-test findings and identification of the actual needs of the children knowledge regarding to prediabetes and diabetes stage. Accordingly, the educational program was designed by the researchers using simple Arabic language and different illustrated pictures in order to facilitate subjects’ understanding.

-Third Phase (Planning and Implementation):

General and specific objectives of educational program were stated and implemented to satisfy the actual needs of the study subjects; evaluation was carried out immediately after the implementation of the educational program by using the same pretest format as a post test.

- Fourth Phase:

Follow up of the educational program was carried out in 4 weeks by using the same pre and post test tools.

Statistical analysis

The collected data were organized, tabulated and analyzed using electronic computer and statistical package for social sciences (SPSS) version 21. Descriptive statistics were calculated for the data in the form of: Mean and standard deviation for quantitative data, and frequency and distribution for qualitative data. Also in analytical statistics, inter-group comparison of categorical data was performed by using chi square test ($X^2$ value). Also, Pearson correlation coefficient test was used. P value $<0.05$ was considered statistically significant (*) while $>0.05$ statistically insignificant and P value $<0.01$ was considered highly significant (**) in all analyses.

Table (5): Evident that, more than half of children who participated in the current study had poor knowledge in preprogram implementation. However, after the application of the programs, the majority of children had good knowledge. There were statistically significant differences between children’ knowledge in the pre- and post-program.
Discussion

Diabetes mellitus is one of the leading chronic diseases of childhood and adolescence. Although type 1 diabetes is the most common form in children, type 2 diabetes mellitus (T2DM) poses a major health problem globally, especially in many developing countries. Type 2 diabetes mellitus in children is probably under-diagnosed because it can exist without symptoms. Early identification of children with prediabetes aids in appropriate management thereby reducing the incidence of diabetes (Dnarayanappa, et al., 2011). The prevalence of obesity, particularly severe obesity, in all pediatric age groups has been accompanied by prediabetes, and insulin resistance (IR) and increase risk of type 2 diabetes mellitus (T2DM). Along with other comorbidities of obesity, including hypertension, dyslipidemia, fatty liver disease, musculoskeletal disorders, and cardiovascular disease, T2DM and its complications represent a significant cause of long-term disability (Colberg et al., 2011).

According to children age, this study illustrated that mean age of studied children 11.3 ± 2.41 years and more than half of studied children were female, same percentage were engaged in preparatory school and more than half were living in urban areas. This result accordance with finding of Weinbery, (2013), which study entitled “sports and fats, blood”, who reported that the incidences of diabetes on world are the rise, the most of children are affected by type 1 diabetes in childhood. The number of children and young adults affected by type 2 diabetes is beginning to rise. This result accordance with Eklioglu et al., (2011), which study entitled “prediabetes and cardiovascular parameters in obese children and adolescents”, the prevalence of prediabetes was 4.5% in the obese children. The mean age was 11.8 ± 2.5 years in prediabetes children.

As regards children knowledge regarding pre-diabetes, this study showed that the highest percentages of children who participated in the current study had no knowledge as regards the definition, causes, complications and prevention of pre-diabetes before the program implementation. However, after the application of the programs, the
majority of children had knowledge about the previously mentioned issues. There were statistically significant differences between children’ knowledge in the pre- and post-program. This results in accordance with Hagman, (2014), which study entitled “elevated fasting glucose levels in obese children and adolescents”, who reported that the pre-diabetes stage is the period before the onset of type II diabetes, but not all children in the pre-diabetes stage suffering from type II diabetes. In the pre-diabetes stage the blood sugar levels high than normal, not considered children suffering from diabetes but at risk to incidence of diabetes.

According to studied children knowledge toward nutrition, this study clarified that the highest percentages of children who participated in the current study had no knowledge as regards the food should be avoided, food should be taken, content of balanced meals and number of meals before the program. However, after the application of the programs, majority of children had knowledge about the previously mentioned issues. There were statistically significant differences between children’ knowledge in the pre- and post-program. These study accordance with Simon, (2014), which study entitled “diabetes”, who revealed that most children have an increased weight resulting from poor dietary habits and lack of exercise can contribute to insulin resistance. This study a accordance with Stefanaki et al., (2014), which study entitled “prediabetes and adolescents trends causes, effects and screening”, who founded that an indisputable association between unhealthy diet behaviors, such as increased junk food consumption, sweetened beverages, reduced consumption of fiber, lower energy intake from snack episodes, breakfast skipping, and energy density of foods have been accompanied by a rise in the prevalence of obesity and prediabetes. This result accordance with Tsenkova, (2014), which study entitled “childhood socioeconomic disadvantage and prediabetes and diabetes in later life”, who reported that a healthy eating plan for losing weight and reducing the risk of type 2 diabetes should include a reduction in total energy, fat intake, particularly foods containing saturated fat such as butter, full fat dairy products, fatty meats, take away foods, biscuits, cakes and pastries. Instead choose a wide range of high fiber, moderate carbohydrate foods such as wholegrain breads and cereals, and fruit.
According to studied children knowledge toward obesity, this study revealed that the highest percentages of children who participated in the current study had no knowledge as regards the definition, causes, complications and treatment of obesity before the program implementation. However, after the application of the programs, the majority of children had knowledge about the previously mentioned issues. There were statistically significant differences between children’ knowledge in the pre- and post-program. This result accordance with finding of Hagman, (2011), who reported that the prevalence of childhood obesity in recent decades within a relatively genetic factors are not the primary cause. The important factors for childhood obesity prevalence include: societal factors, such as the marketing of energy-dense foods on television, socioeconomic factors, such as income inequality, physical inactivity, and dietary habits, such as more widespread food purchasing opportunities, larger portion size, junk food consumption and sugar-sweetened beverages. However, other factors, such as viral infections may also contribute to the development. In addition, this study agreement with Eklioglu et al., (2014), which study entitled “prediabetes and cardiovascular parameters in obese children and adolescents”, Who reported that when insulin secretion cannot maintain the degree of hyperinsulinemia required to overcome the resistance, prediabetes impaired glucose tolerance (IGT), impaired fasting glucose and subsequently T2DM develop.

Also, this study accordance with Dnarayanappa, et al., (2011), which study entitled “prevalence of prediabetes in school-going children”, who reported that positive association between obesity (overweight) and risk of type 2 diabetes has been established repeatedly in many cross-sectional and prospective studies and increasing prevalence of type 2 diabetes among children in India and other countries has been attributed to epidemic of obesity and overweight among children.

As regards studied children knowledge regarding exercise, this study illustrate that the highest percentages of children who participated in the current study had no knowledge as regards the importance of exercise, effort and hyperactivity should be avoided and type of exercise and
normal range of exercise per day before the program implementation. However, after the application of the programs, the majority of children had knowledge about the previously mentioned issues. There were statistically significant differences between children’ knowledge in the pre- and post-program. This result accordance with Health Care and Education Committee of Diabetes Australia, (2011), which study entitled “prediabetes (IFG & IGT)”, who reported that exercises can help insulin enter in to membranes of muscle cells, facilitates the entry of glucose in to muscles, and prove that the insulin is responsible for glucose transport during physical exercise and these exercises increase the influence of insulin and should be take into account reduce calories intake in the meal. Regular physical activity such as brisk, walking or swimming) every day or three, 21 minute sessions of exercise per week (such as aerobics class, strenuous gardening) helps body to use insulin better and to feel fit and healthy. Starting a regular physical activity program and sticking to it can often be made a lot easier by joining up with a group or motivated friend to encourage keeping continuously performance.

According to children physical examinations, this study described that there was a highly statistically significant difference observed between the studied children blood pressure, children weight and body mass index and blood sugar test at pre and post program implementation. This result accordance with finding of Simon, (2011), who reported that diabetes is a chronic illness that requires continuing medical care and support to prevent acute complications and to reduce the risk of long-term complications. Also, this result accordance with Preneet et al., (2011), which study entitled “screening obese children and adolescents for prediabetes/type diabetes in pediatric practices”, who reported that, the childhood obesity epidemic has led to an increase in type diabetes in children and youth. The children have shown that rates of prediabetes should be early detection in particular is key to restoring normal glucose tolerance (NGT) because use of lifestyle modification and/or medications such as metformin or both, have proven to be effective in reversing prediabetes. Therefore, defining effective screening tools for pediatricians is an important task and validating these measures against a diagnostic
standard such as OGTT and recommends screening at-risk children using fasting plasma glucose (FPG) or oral glucose tolerance test (OGTT) every 2 years starting at 11 years of age or at the onset of puberty.

According to children total knowledge regarding prediabetes, this study illustrated that, more than half of children who participated in the current study had poor knowledge in preprogram implementation. However, after the application of the programs, majority of children had good knowledge. There were statistically significant differences between children’ knowledge in the pre- and post-program. This study agreement with finding of Blasingame, who noted that there was an increase in knowledge of children in 11 out of 16 questions. The questionnaire contained multiple choice questions pertaining to harm of obesity, benefits of physical activity, and the recommendations related to diet and exercise. With a significance level <.0.05, question number 4 had a significance level of (p=.0.011) and question 11 had a significance level of (p=.0.011). The majority (n=14) failed 4 out of the 16 questions on the pretest. Surprisingly, using 415 as passing score for the posttest, all of the participants scored a passing rate. It was noted participants posttest answered question 11 with an increase of 66±5 in the post-test. Question number 4 (pre-test) was the second most missed question with only 46±5 answering it correctly. Question number 4 asked, the American Heart Association recommends that children and teenagers get at least 45 minutes of exercise per day. Post-test there was an increase of students answering question 4 correctly scoring 93%.

In my opinion obesity among children become most common problems, obesity can lead to type diabetes mellitus and parents not having any knowledge about periodic laboratory test should be done for children to detect elevation of blood glucose and methods to prevent complication.

Conclusion

Studied children in pre-diabetes period their knowledge was upgrading after implementation of the health education program were improved especially for diet, obesity and personal hygiene, exercise, laboratory
examination and physical examination. Meanwhile, there were improvement in blood sugar level, blood pressure and decrease body weight as compared to preprogram. This improvement result from educational program offered. Education may be a tool used to empower and challenge youth to take a stand to live healthier while preventing chronic diseases.

Recommendations

- Continuous health education program should be provided for obese children to prevent occurrence of diabetes mellitus
- Further research to be carried out regarding prediabetes in children because diabetes has become a major public health problem in Egypt.
- School nurse should be monitoring blood glucose level for obese children to prevent occurrences of type two diabetes mellitus (T2D).
- The guidelines also recommend the compulsory analyzed blood sugar test for obese or overweight children every year.
- Further research is needed to guide which therapies might best prevent progression of prediabetes to T2DM among children
- Mass media should play a vital role in increasing awareness about prediabetes, methods of its prevention and its treatment.
