**ABSTRACT**
The present study was conducted to evaluate the protective effect of Spirulina on mycotoxins induced liver damage and oxidative stress in rats. Thirty male albino rats were classified randomly into three equal groups. Group1(normal control): Rats fed with ordinary diet. Group2 (Mycotoxin): Rats fed with ordinary ration only for first 7 days and from day 8 rats fed mixed ration contain 50 gram of grinded plant (total aflatoxins 4.2 ppb) + 50 gram of grinded fish (total aflatoxins 42.14 ppb) + 50 gram of ordinary diet (free of aflatoxins) for 4 weeks. Group3 (Mycotoxin+ Spirulina): Spirulina Platensis (500 mg/kg b.wt/day) was administered orally all over the experimental period (5 weeks). Also, rats were fed on ordinary diet only for first 7 days and from day 8 rats fed mixed ration as that mentioned above in group 2. At the end of the experiment liver tissue specimens were isolated and analyzed for the determination of reduced glutathione (GSH), superoxide dismutase (SOD), catalase (CAT), L-malondialdehyde (L-MDA) in addition to interleukin-1(IL-1) gene expression and DNA damage. The obtained results showed a significant up-regulation of IL-1 gene expression level and marked increase in SOD, CAT, L-MDA and DNA damage that was indicated by an increase in tail length and tail DNA % in liver tissue of mycotoxin rats group. However, liver GSH concentration was markedly decreased as compared to control group. Spirulina protected mycotoxins induced liver damage in rats caused a significant improvement of all previous parameters and attenuates DNA changes. Conclusively, Spirulina Platensis treatment exerts a protective effect against DNA damage and oxidative stress in liver of mycotoxin intoxicated rats through free radical scavenging and anti-inflammatory activities as well as regenerating endogenous antioxidants defense system mechanisms.

**Keywords:** Mycotoxins, liver damage, *Spirulina platensis*, oxidative stress.

1. INTRODUCTION
Mycotoxins are secondary metabolites produced by a wide range of fungi known to contaminate a variety of food and agricultural commodities worldwide. Their occurrence in food, beverages and feed has been recognized as potential threat to humans and animals, either by direct contamination of plant materials or products [1], or by “carry over” of mycotoxins and their metabolites into animal tissues, milk and eggs after intake of contaminated feed. Mycotoxins have carcinogenic, mutagenic, teratogenic, immunosuppressive and tremorgenic effects [2]. Over 400 mycotoxins are known and the foodborne toxins of most interest are aflatoxins B1 (AFB1), aflatoxins B2 (AFB2), aflatoxins G1 (AFG1), aflatoxins G2 (AFG2), trichotheccenes, fumonisins(FB1 and FB2), ochratoxin A (OTA), zearalenone (ZEN) and Alternaria toxins, due to their frequent occurrence and their severe effects on animal and human health [3].

*Spirulina* (SP), is symbiotic, multicellular and filamentous cyanobacterium (blue–green alga), that has free-floating filamentous microalgae with spiral characteristics of its filaments and symbiotic bacteria that fix nitrogen from air. It is formally called...
Arthrospira, belonging to Phylum: Cyanobacteria, Class: Cyanobacteriaceae, Order: Nostocales, Family: Oscillatoriaceae, Genus: Spirulina with characteristic photosynthetic capability [4]. Among large number of Spirulina species, three species of Spirulina, including Spirulina platensis (Arthrospira platensis), Spirulina maxima (Arthrospira maxima) and Spirulina fusiformis (Arthrospira fusiformis) are most intensively investigated as those Spirulina species are edible with high nutritional as well as potential therapeutic values. One of these, Arthrospira platensis is the most common and widely available spirulina and most of the published research and public health decision refers to this specific species [5]. Spirulina contains proteins (up to 70 % protein of dry weight), lipids (contain 5-8% lipid), carbohydrates( up to 14 %), some vital minerals (like calcium, iron, zinc, magnesium, manganese, selenium), essential fatty acids, polysaccharides, glycolipids (contain 40%), sulpholipids (2-5%), vitamins including B-carotene, a precursor of vitamin A, substantial amounts of carotenes stimulate the immune system and reduce toxic effects of radiation and chemotherapy [6].

Accordingly, the present study was carried out to investigate the harmful exposure effect of mycotoxins in rats and trials for ameliorating these mycotoxins effect using blue green algae (Spirulina).

2. MATERIALS AND METHODS

2.1. Experimental animals:
Thirty white male albino rats of 4-5-weeks old and average body weight 100-130 g were used in this study. Rats were obtained from Laboratory Animals Research Center, Animal health research animal institute, Dokki, Cairo. Rats were housed in separated polycarbonate cages (10 per cage) and they were kept on a well-balanced ration and fresh clean drinking water ad libitum. Rats were kept at a constant environmental and nutritional condition throughout the whole period of experiment. All rats were left for 15 days for acclimatization before the beginning of the experiment.

2.2. Natural medical plant:
2.2.1. Spirulina platensis
Spirulina microalgalae blue green powder was obtained from Cairo National Research Center – Dokki-Egypt.
Preparation and dosage of Spirulina:
Spirulina was freshly prepared by dissolved in distilled water and administered orally using stomach tube in a daily dose of 500 mg/kg body weight [7].

2.3. Experimental design:
After acclimatization to the laboratory conditions, the animals were randomly classified into three groups (10 rats each) placed in individual cages and classified as follows:

Group 1 (control group): Rats fed with ordinary diet (free of mycotoxin) only without any treatment during the entire experimental period of 5 weeks.

Group 2 (Mycotoxin group): Rats fed with ordinary diet only for first 7 days and from day 8 rats fed mixed ration containing 50 grams of grinded plant (total aflatoxins 4.2 ppb) + 50 grams of grinded fish (total aflatoxins 42.14 ppb) + 50 grams of ordinary diet (free of aflatoxins) for 4 weeks.

Group 3 (mycotoxin + Spirulina group): Spirulina platensis (500 mg/kg bwt/day) was administered orally all over the experimental period (5 weeks). Also, rats fed with ordinary diet only for first 7 days and from day 8, rats fed mixed ration containing 50 grams of grinded plant (total aflatoxins 4.2 ppb) + 50 grams of grinded fish (total aflatoxins 42.14 ppb) + 50 grams of ordinary diet (free of aflatoxins) for 4 weeks.

2.4. Sampling:
Liver tissue specimens were collected from all animal groups (control and experimental groups) once after the end of 5 weeks.

2.4.1. Tissue samples for biochemical analysis:-
At the end of the experiment the rats were sacrificed under light ether anesthesia. Liver tissues were isolated immediately, weighed and then one of them was cleaned by rinsing with cold saline and stored at -20 ºC for subsequent biochemical analysis. All liver samples were analyzed for the determination of reduced Glutathione (GSH), superoxide dismutase (SOD), catalase (CAT) and L-malondialdehyde (L-MDA).

2.4.1.1. Liver tissue preparation for biochemical analysis:-
Liver tissues were cut, weighed and minced into small pieces, homogenized with a glass homogenizer in 9 volume of ice-cold 0.05 mM potassium phosphate buffer (pH7.4) to make 10% homogenates. The homogenates were centrifuged at 6000 r.p.m for 15 minutes at 4 ºC then the resultant supernatant was used for the determination of the following parameters: L-MDA, SOD and CAT.

About 0.2 g of liver tissues were minced into small pieces homogenized with a glass homogenizer in 0.4 ml of 25% metaphosphoric acid (MPA), (ref. No.: 253-433-4, Sigma-Aldrich, Germany), then 1.4 mL of distilled water was added, mixed, incubated for 1 hour and centrifuged for 10 min at 3,000 r.p.m then the clear supernatant was removed and used for determination of GSH concentration.

2.4.1.2. Liver tissue preparation for molecular analysis:
Liver tissue was immediately excised and frozen in liquid nitrogen and then in -80ºC until used for determination of DNA damage using comet assay and interleukin-1(IL-1) gene expression analysis by qPCR.

2.5. Analysis:
2.5.1. Biochemical analysis:
Liver tissue L-MDA, superoxide dismutase (SOD), catalase (CAT) and reduced glutathione (GSH) were determined according to the method adapted by

http://ijps.aizeonpublishers.net/content/2019/2/ijps2039-2044.pdf
2.5.2. Molecular analysis:
Total RNA was isolated from liver tissue of rats using RNeasy Mini Kit (Thermo Scientific, Fermentas, #K0731) according to the manufacturer’s protocol. Following determination of RNA concentration and purity by Quawell nanodrop Q5000 (USA), 5 mg of total RNA from each sample was reverse transcribed using Quantiscript reverse transcriptase. The produced cDNA was used as a template to determine the relative expression of Interleukin-1 gene using StepOnePlus real time PCR system (Applied Biosystem, USA) and gene specific primers. The reference gene, β actin, was used to calculate fold change in target genes expression. The thermal cycling conditions, melting curves temperatures, and calculation of relative expression was done. For the treated groups, assessment of 2^-ΔΔCt determined the fold change in gene expression relative to the control.

Also, DNA damage was estimated by alkaline single-cell gel electrophoresis (comet assay) according to the protocol described by Singh et al., (1988) [12].

2.6. Statistical analysis:
The results were expressed as mean ± SE using SAS computerized program v. 9.2 [13] program to calculate the analysis of variance. The data were analyzed using one-way ANOVA to determine the statistical significance of differences among groups. Duncan’s test was used for making a multiple comparisons among the groups for testing the inter-grouping homogeneity. Values were considered statistically significant when p<0.05.

3. RESULTS AND DISCUSSION
3.1 Changes in relative expression of IL-1β gene in liver tissues of mycotoxin -intoxicated rats after spirulina treatment:
The qPCR results (Table 1) revealed a significant up-regulation of IL-1β gene expression level in livers of mycotoxin treated rats as compared to control group. This expression was significantly down-regulated following treatment by spirulina.

Data are presented as means ± Standard Error (S.E)
Means values with different superscript letters in the same row are significantly different at (P<0.05). (n = 5) in each group.
3.2 Effects of spirulina against mycotoxins induced changes on liver tissue GSH, SOD, Catalase and L-MDA in male rats:

The obtained results presented in table (2) revealed that, the mean values of liver reduced glutathione (GSH) concentration significantly decreased in mycotoxin group in comparison with control group. Pretreatment with spirulina group (3) significantly increased liver GSH concentration in comparison with mycotoxin group.

The mean values of liver SOD and CAT activities significantly increased in mycotoxin group in comparison with control group. Pretreatment with spirulina group (3) significantly decreased liver SOD and CAT activities when compared with mycotoxin treated rats only.

Exposure of mycotoxin via food in normal rats caused significant increase in the value of liver L-MDA concentration in comparison with control group. Pretreatment with spirulina caused significant decrease in liver L-MDA concentration.

Figure 1: Photomicrographs representation of DNA damage, using comet assay, in normal control group, mycotoxin group and Spirulina treated group.

3.3 Comet assay parameters obtained by image analysis in rat liver:

The obtained results of DNA damage presented in table(3) and the figure (1) showed that, exposure of mycotoxin via food induced significant increase in DNA damage; indicated by an increase in tail length and tail DNA % in liver tissue of mycotoxin intoxicated rats as compared to control group. DNA damage was significantly lowered in spirulina treated rats as compared to mycotoxin group.
Mycotoxins are toxic chemicals formed as secondary metabolites of fungi. They are frequently consumed in food products from crops origin, such as cereals, nuts, dried fruits, spices, oil seeds, beans, fruits, beer and wine [14]. The contamination of animal, fish and human foods with mycotoxins represent a worldwide problem constituting a real threat to the health of livestock for animals, aquaculture industry and human by the continuing intermittent occurrence in their feeds [15]. Spirulina can be a very interesting natural source of new compounds with biological activity that could be used as functional ingredients. The cyanobacterium Spirulina is used as food by humans because of its chemical composition, which has high quality and quantity of proteins, essential amino acids, minerals, polyunsaturated fatty acids and vitamins. It has been reported to prevent oxidative damage, and hence can indirectly reduce cancer formation in human body [16].

The obtained qPCR results revealed a significant up-regulation of IL-1β gene expression level in livers of mycotoxin rats as compared to control group. These results are nearly similar with the recorded data of Albarenque et al., (2001) [17] who suggested that, the expression of pro-inflammatory cytokines IL-1β was increased in the T-2 toxin-treated cells cultures throughout the experimental period. Likewise, Abdel-Wahhab et al., (2006) [18] postulated that, the ingestion of aflatoxins B1 (AFB1) significantly increased IL-1β suggesting that AFB1 preferentially affects macrophage functions. The expression of IL-1β gene was significantly down-regulated following treatment by spirulina. This suggestion was supported by the findings of Hörl, (2010) [19] who reported that, Spirulina extract also extensively inhibit the inflammatory cascade by effectual modulation of inflammatory cytokines (IL-1), thus curbing the further exacerbation of mycotoxin renal injury mediated by inflammatory cytokines.

The obtained results revealed that, the main value of liver reduced glutathione (GSH) concentration was significantly decreased in mycotoxin group in comparison with control group. These results were in harmony with those of Stockmann-Juvala et al., (2004) [20] who concluded that, oxidative stress and apoptosis may be involved in the neurotoxicity induced by AFB1, which caused disturbance of GSH generation. According to Umarani et al., (2008) [21] who showed that a significant reduction in the levels of hepatic GSH was observed in the AFB1 group. This depletion of liver GSH may be attributed to its conjugation with the electrophilic metabolites. Pretreatment with spirulina group significantly increased serum GSH concentration in comparison with mycotoxin group. These results were nearly similar with Hassan et al., (2012) [22] who evaluated the ability of Spirulina to counteract oxidative stress in rats with mycotoxin-induced aflatoxicosis. Supplementation with Spirulina led to a significant reduction in aflatoxin-induced oxidative stress, as revealed by increased GSH content. Meanwhile, Abd El-Baky et al., (2009) [23] recorded that Spirulina platensis maintained the activity of cellular antioxidant enzymes under oxidative stress and increased the level of reduced glutathione in these cells.

The results of the current study revealed that, mycotoxin treated rats significantly increased liver superoxide dismutase (SOD) and catalase (CAT) activities in comparison with control group. These results came in accordance with the recorded data of Chaudhary and Rao (2010) [24] who reported that, mycotoxin treated animals increasing ROS generation showed significant increase in the gene expression profile of antioxidant enzymes SOD and CAT. Pretreatment with spirulina significantly decreased liver SOD and CAT activity when compared with mycotoxin treated rats only. Likely, Qing et al., (2003) [25] found that, the activity of two antioxidant enzymes contained within Spirulina maxima, superoxide dismutase (SOD) and catalase (CAT), increased under conditions of light stress, although SOD was more sensitive to external stress than CAT.

The recorded data showed significant increase in the value of liver tissue L-MDA in mycotoxicated rats when compared with normal control group. These results agreed well with those of Chaudhary and Rao, (2010) [24] who reported that, T2 toxin-treated rats showed a time-dependent increase in ROS generation and marked increase in lipid peroxidation in the kidney during oral administration of Aflatoxin for 30 days.

Pretreatment with spirulina caused significant decrease in liver L-MDA concentration. These results were similar with the recorded data of Yoshikawa and Naito, (2002) [26] who stated that, treatment with Spirulina significantly reduced oxidative stress and L-malondialdehyde in mycotoxin intoxicated rats. Reactive oxygen species (ROS) attacked and damaged molecules in biological systems, leading to oxidative stress and various disorders and diseases occur. The antioxidant potential of Spirulina species and protective effects were mediated by phycocyanins, β-carotene, and other vitamins and minerals contained within Spirulina [27]. Moreover, Bermejo et al., (2008) [28] reported that, phycocyanin appear to inhibit the generation of hydroxyl and peroxyl radicals, as well as lipid peroxidation.

4. CONCLUSION

From the obtained results it could be concluded that, Spirulina Platensis protect the liver from mycotoxin induced oxidative stress and tissue damage. The protective effect of spirulina might be mediated by adjustment of inflammatory mediators and increasing antioxidants as well as attenuating oxidant/antioxidant imbalance. It seems likely that spirulina enriched in phenolic compounds contains no hepatotoxicity. So, its possible potential as a promising natural therapeutic agent in liver damage and other diseases associated with oxidative stress.
